

Appendix 1

.1 Process Models.

In this section, we provide the reference process models for the BPIC'12 real-event data [34] and the synthetic event data of [26].

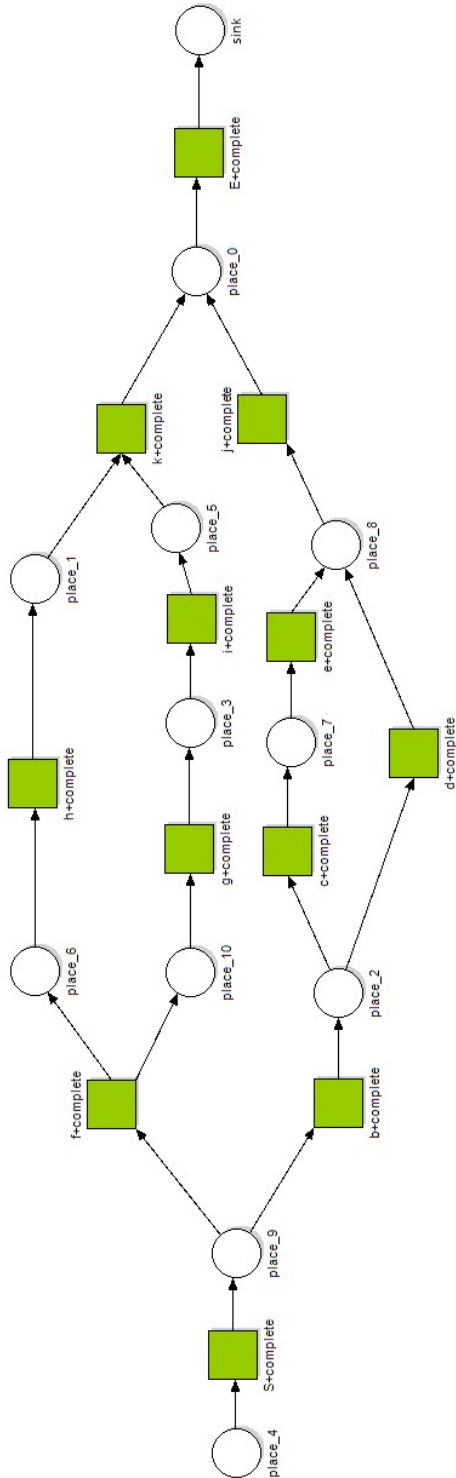

Figure 2: Process model of *q12* synthetic event data [26].

Figure 5: An example flower process model.

Appendix 2

.1 Model-Based Prefix Imputation(PMc).

In this section, we provide the complete set of results for the experiments with $a12$, $a22$, and $a32$ synthetic events logs for the PMc stateless approach.

(a) Skewness of decisions level 0

(b) Skewness of decisions level 1

(c) Skewness of decisions level 2

Figure 6: Percentage reduction in memory footprint w.r.t. the baseline (BL) for $a12$ event logs with different skewness of decisions and noise levels with PMc as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The value n on the X-axis is the maximum number of cases allowed to be retained in D_C . The number on the secondary Y-axis is the maximum states consumed by the baseline (BL).

(a) Skewness of decisions level 0

(b) Skewness of decisions level 1

(c) Skewness of decisions level 2

Figure 7: Percentage reduction in memory footprint w.r.t. the baseline (BL) for *a22* event logs with different skewness of decisions and noise levels with *PMc* as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The value n on the X-axis is the maximum number of cases allowed to be retained in D_C . The number on the secondary Y-axis is the maximum states consumed by the baseline (BL).

(a) Skewness of decisions level 0

(b) Skewness of decisions level 1

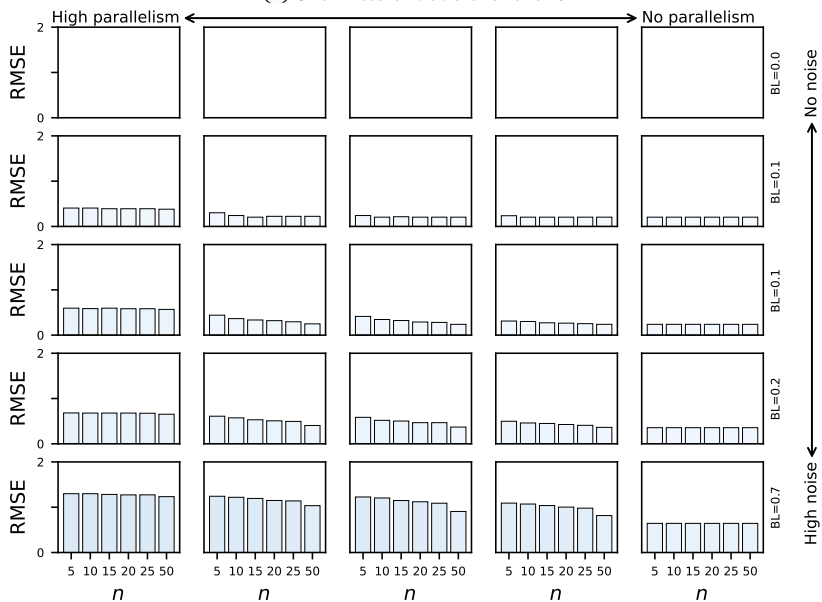

(c) Skewness of decisions level 2

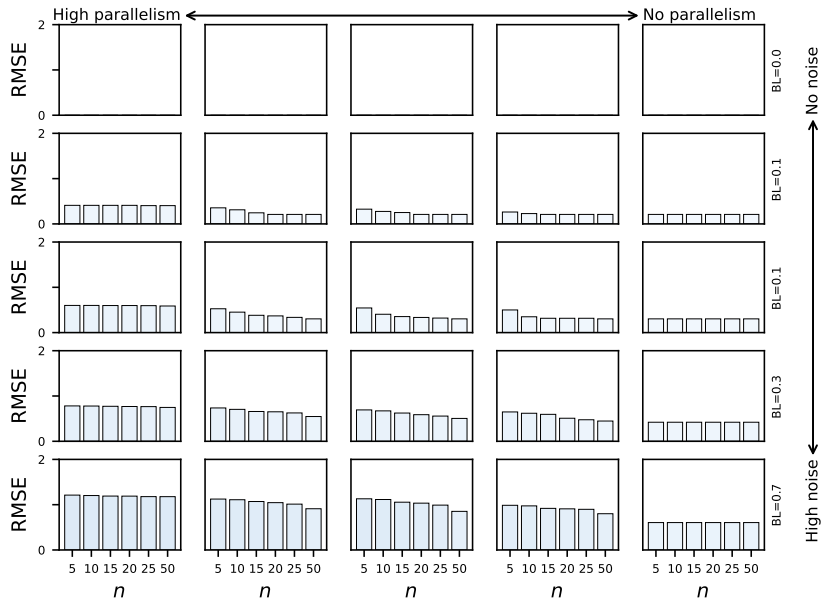

Figure 8: Percentage reduction in memory footprint w.r.t. the baseline (BL) for $a32$ event logs with different skewness of decisions and noise levels with PMc as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The value n on the X-axis is the maximum number of cases allowed to be retained in D_C . The number on the secondary Y-axis is the maximum states consumed by the baseline (BL).

(a) Skewness of decisions level 0

(b) Skewness of decisions level 1

(c) Skewness of decisions level 2

Figure 9: RMSE for a_{12} event logs with different decision skewness and noise levels with PMc as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The number on the secondary Y-axis is the avg. trace fitness cost over the log by the baseline(BL).

(a) Skewness of decisions level 0

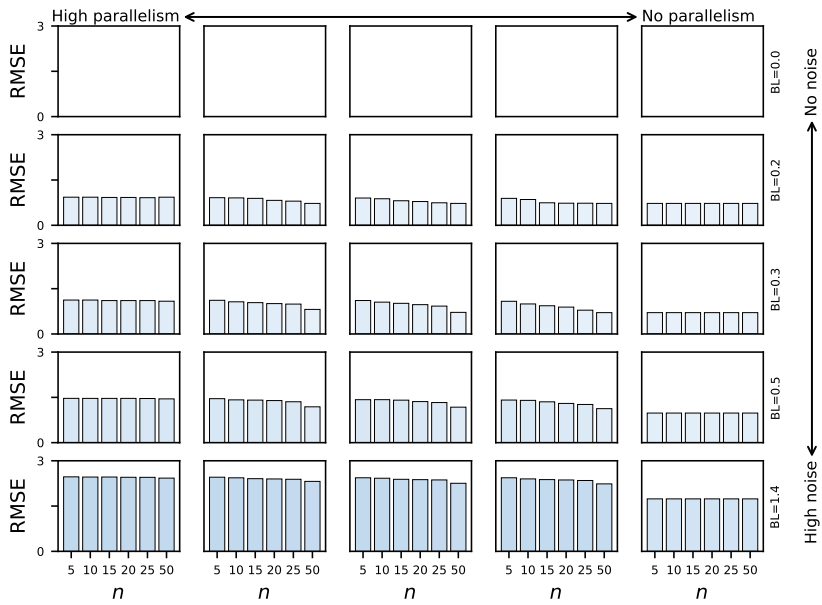

(b) Skewness of decisions level 1

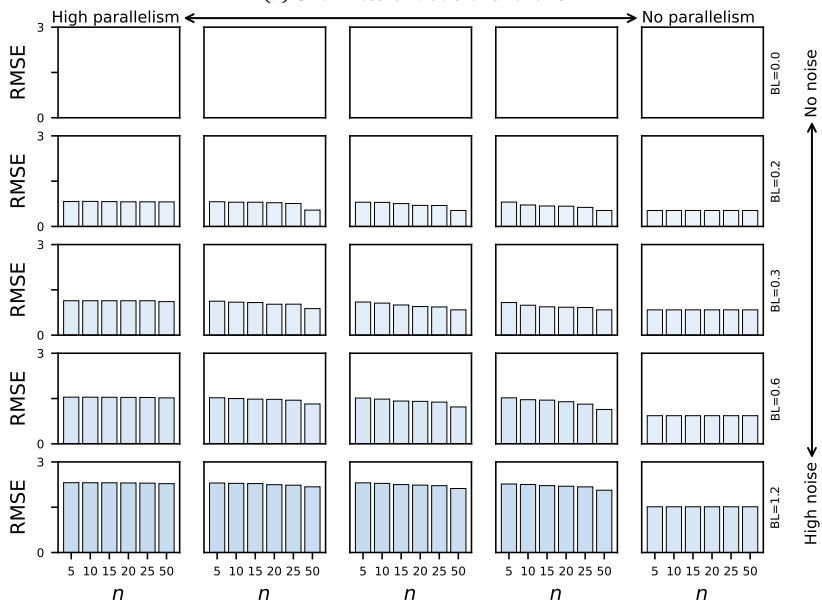

(c) Skewness of decisions level 2

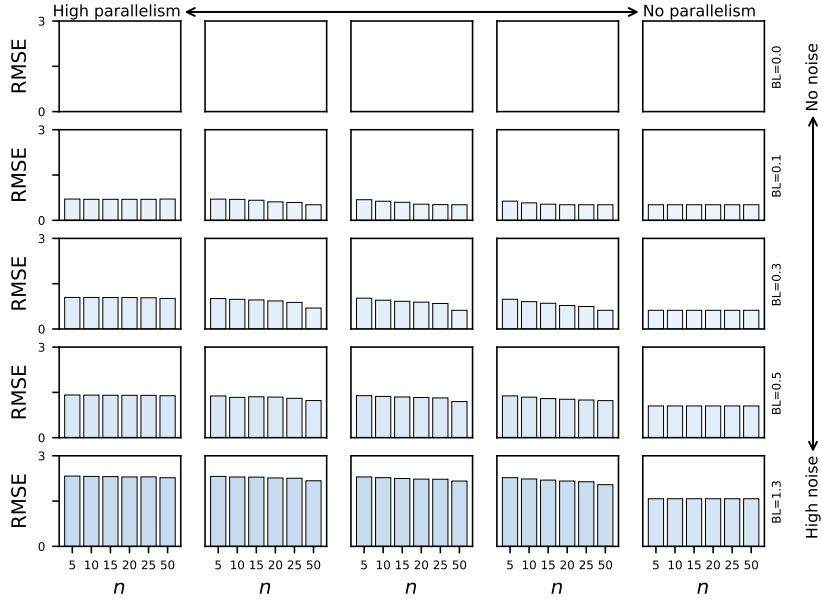

Figure 10: RMSE for *a22* event logs with different decision skewness and noise levels with *PMc* as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The number on the secondary Y-axis is the avg. trace fitness cost over the log by the baseline(BL).

(a) Skewness of decisions level 0

(b) Skewness of decisions level 1

(c) Skewness of decisions level 2

Figure 11: RMSE for $a32$ event logs with different decision skewness and noise levels with PMc as a heatmap. A dark color represents the worst value of the respective metric, while brighter colors encapsulate its best values. The number on the secondary Y-axis is the avg. trace fitness cost over the log by the baseline(BL).
